1 GENERAL DESCRIPTION

SSD1306 is a single-chip CMOS OLED/PLED driver with controller for organic / polymer light emitting diode dot-matrix graphic display system. It consists of 128 segments and 64commons. This IC is designed for Common Cathode type OLED panel.

The SSD1306 embeds with contrast control, display RAM and oscillator, which reduces the number of external components and power consumption. It has 256-step brightness control. Data/Commands are sent from general MCU through the hardware selectable 6800/8000 series compatible Parallel Interface, I²C interface or Serial Peripheral Interface. It is suitable for many compact portable applications, such as mobile phone sub-display, MP3 player and calculator, etc.

2 FEATURES

- Resolution: 128 x 64 dot matrix panel
- Power supply
 - \circ V_{DD} = 1.65V to 3.3V for IC logic
 - o $V_{CC} = 7V$ to 15V for Panel driving
- For matrix display
 - o OLED driving output voltage, 15V maximum
 - o Segment maximum source current: 100uA
 - Common maximum sink current: 15mA
 - o 256 step contrast brightness current control
- Embedded 128 x 64 bit SRAM display buffer
- Pin selectable MCU Interfaces:
 - o 8-bit 6800/8080-series parallel interface
 - o 3 /4 wire Serial Peripheral Interface
 - o I²C Interface
- Screen saving continuous scrolling function in both horizontal and vertical direction
- RAM write synchronization signal
- Programmable Frame Rate and Multiplexing Ratio
- Row Re-mapping and Column Re-mapping
- On-Chip Oscillator
- Chip layout for COG & COF
- Wide range of operating temperature: -40°C to 85°C

3 ORDERING INFORMATION

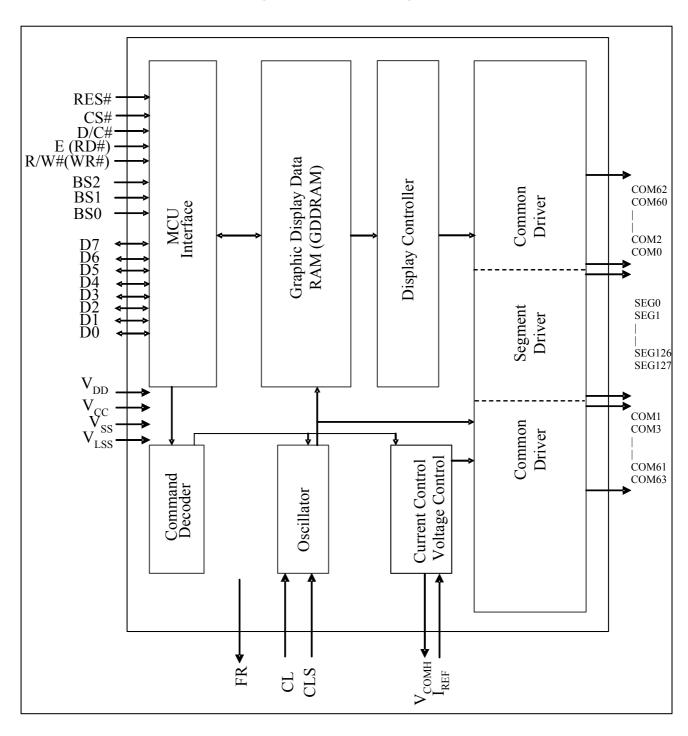

Table 3-1: Ordering Information

| Ordering Part Number | SEG | COM | Package Form | Reference | Remark |
|----------------------|-----|-----|--------------|-----------|---|
| SSD1306Z | 128 | 64 | COG | 8 | Min SEG pad pitch: 47um Min COM pad pitch: 40um Die thickness: 300 +/- 25um |
| SSD1306TR1 | 104 | 48 | TAB | 11, 56 | 35mm film, 4 sprocket hole, Folding TAB 8-bit 80 / 8-bit 68 / SPI / I²C interface SEG, COM lead pitch 0.1mm x 0.997 =0.0997mm Die thickness: 457 +/- 25um |

7 PIN DESCRIPTION

Key:

| I = Input | NC = Not Connected |
|-------------------------------------|---------------------------------------|
| O =Output | Pull LOW= connect to Ground |
| I/O = Bi-directional (input/output) | Pull HIGH= connect to V _{DD} |
| P = Power pin | |

Figure 7-1 Pin Description

| Pin Name | Type | Description |
|---------------------|------|--|
| $V_{ m DD}$ | P | Power supply pin for core logic operation. |
| V _{CC} | P | Power supply for panel driving voltage. This is also the most positive power voltage supply pin. |
| V _{SS} | P | This is a ground pin. |
| V _{LSS} | P | This is an analog ground pin. It should be connected to V_{SS} externally. |
| V _{COMH} | О | The pin for COM signal deselected voltage level. A capacitor should be connected between this pin and $V_{\rm SS}$. |
| V_{BAT} | P | Reserved pin. It should be connected to V _{DD} . |
| BGGND | P | Reserved pin. It should be connected to ground. |
| C1P/C1N C2P/C2N | I | Reserved pin. It should be kept NC. |
| V_{BREF} | P | Reserved pin. It should be kept NC. |
| BS[2:0] | I | MCU bus interface selection pins. Please refer to Table 7-1 for the details of setting. |
| I_{REF} | I | This is segment output current reference pin. A resistor should be connected between this pin and V_{SS} to maintain the I_{REF} current at 12.5 uA. Please refer to Figure 8-15 for the details of resistor value. |
| FR | 0 | This pin outputs RAM write synchronization signal. Proper timing between MCU data writing and frame display timing can be achieved to prevent tearing effect. It should be kept NC if it is not used. Please refer to Section 8.4 for details usage. |
| CL | I | This is external clock input pin. When internal clock is enabled (i.e. HIGH in CLS pin), this pin is not used and should be connected to V _{SS} . When internal clock is disabled (i.e. LOW in CLS pin), this pin is the external clock source input pin. |
| CLS | I | This is internal clock enable pin. When it is pulled HIGH (i.e. connect to $V_{\rm DD}$), internal clock is enabled. When it is pulled LOW, the internal clock is disabled; an external clock source must be connected to the CL pin for normal operation. |
| RES# | I | This pin is reset signal input. When the pin is pulled LOW, initialization of the chip is executed. Keep this pin HIGH (i.e. connect to V_{DD}) during normal operation. |
| CS# | I | This pin is the chip select input. (active LOW). |

SSD1306 Rev 1.1 P 13/59 Apr 2008 **Solomon Systech**

| Pin Name | Type | Description |
|------------------|------|---|
| D/C# | I | This is Data/Command control pin. When it is pulled HIGH (i.e. connect to V_{DD}), the data at D[7:0] is treated as data. When it is pulled LOW, the data at D[7:0] will be transferred to the command register. In I ² C mode, this pin acts as SA0 for slave address selection. When 3-wire serial interface is selected, this pin must be connected to V_{SS} . For detail relationship to MCU interface signals, please refer to the Timing Characteristics Diagrams: Figure 13-1 to Figure 13-5 . |
| E (RD#) | I | When interfacing to a 6800-series microprocessor, this pin will be used as the Enable (E) signal. Read/write operation is initiated when this pin is pulled HIGH (i.e. connect to V_{DD}) and the chip is selected. When connecting to an 8080-series microprocessor, this pin receives the Read (RD#) signal. Read operation is initiated when this pin is pulled LOW and the chip is selected. When serial or I^2C interface is selected, this pin must be connected to V_{SS} . |
| R/W#(WR#) | I | This is read / write control input pin connecting to the MCU interface. When interfacing to a 6800-series microprocessor, this pin will be used as Read/Write (R/W#) selection input. Read mode will be carried out when this pin is pulled HIGH (i.e. connect to $V_{\rm DD}$) and write mode when LOW. When 8080 interface mode is selected, this pin will be the Write (WR#) input. Data write operation is initiated when this pin is pulled LOW and the chip is selected. When serial or I^2C interface is selected, this pin must be connected to $V_{\rm SS}$. |
| D[7:0] | IO | These are 8-bit bi-directional data bus to be connected to the microprocessor's data bus. When serial interface mode is selected, D0 will be the serial clock input: SCLK; D1 will be the serial data input: SDIN and D2 should be kept NC. When I²C mode is selected, D2, D1 should be tied together and serve as SDA _{out} , SDA _{in} in application and D0 is the serial clock input, SCL. |
| TR0-TR6 | - | Testing reserved pins. It should be kept NC. |
| SEG0 ~ SEG127 | О | These pins provide Segment switch signals to OLED panel. These pins are V_{SS} state when display is OFF. |
| COM0 ~ COM63 | О | These pins provide Common switch signals to OLED panel. They are in high impedance state when display is OFF. |
| NC | - | This is dummy pin. Do not group or short NC pins together. |

Table 7-1: MCU Bus Interface Pin Selection

| SSD1306 Pin Name | I ² C Interface | 6800-parallel interface (8 bit) | 8080-parallel interface (8 bit) | 4-wire Serial interface | 3-wire Serial interface |
|---------------------|----------------------------|---------------------------------|---------------------------------|-------------------------|-------------------------|

8 FUNCTIONAL BLOCK DESCRIPTIONS

8.1 MCU Interface selection

SSD1306 MCU interface consist of 8 data pins and 5 control pins. The pin assignment at different interface mode is summarized in Table 8-1. Different MCU mode can be set by hardware selection on BS[2:0] pins (please refer to Table 7-1 for BS[2:0] setting).

Table 8-1: MCU interface assignment under different bus interface mode

| Pin Name | Data/0 | Comma | nd Inte | rface | | | | | Contro | l Signal | | | |

| I^2C | Tie LC |)W | | | | SDA _{OUT} | SDA_{IN} | SCL | Tie LO | W | | SA0 | RES# |

8.1.1 MCU Parallel 6800-series Interface

The parallel interface consists of 8 bi-directional data pins (D[7:0]), R/W#, D/C#, E and CS#.

A LOW in R/W# indicates WRITE operation and HIGH in R/W# indicates READ operation. A LOW in D/C# indicates COMMAND read/write and HIGH in D/C# indicates DATA read/write. The E input serves as data latch signal while CS# is LOW. Data is latched at the falling edge of E signal.

Table 8-2: Control pins of 6800 interface

| Function | E | R/W# | CS# | D/C# |
|---------------|----------|------|-----|------|
| Write command | ↓ | L | L | L |
| Read status | ↓ | Н | L | L |
| Write data | ↓ | L | L | Н |
| Read data | ↓ | Н | L | Н |

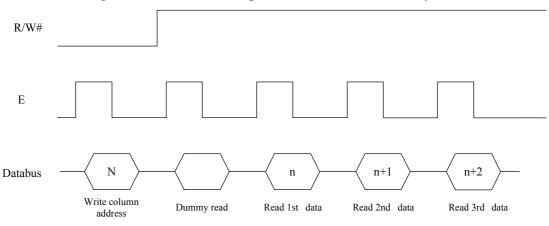

Note

(1) ↓ stands for falling edge of signal H stands for HIGH in signal L stands for LOW in signal

In order to match the operating frequency of display RAM with that of the microprocessor, some pipeline processing is internally performed which requires the insertion of a dummy read before the first actual display data read. This is shown in Figure 8-1.

SSD1306 | Rev 1.1 | P 15/59 | Apr 2008 | **Solomon Systech**

Figure 8-1: Data read back procedure - insertion of dummy read

8.1.2 MCU Parallel 8080-series Interface

The parallel interface consists of 8 bi-directional data pins (D[7:0]), RD#, WR#, D/C# and CS#.

A LOW in D/C# indicates COMMAND read/write and HIGH in D/C# indicates DATA read/write. A rising edge of RD# input serves as a data READ latch signal while CS# is kept LOW. A rising edge of WR# input serves as a data/command WRITE latch signal while CS# is kept LOW.

Figure 8-2: Example of Write procedure in 8080 parallel interface mode

Figure 8-3: Example of Read procedure in 8080 parallel interface mode

Solomon Systech Apr 2008 | P 16/59 | Rev 1.1 | SSD1306

Table 8-3: Control pins of 8080 interface

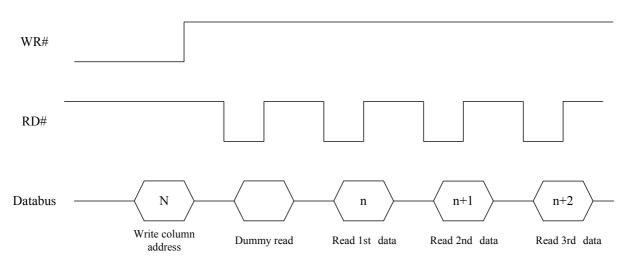

| Function | RD# | WR# | CS# | D/C# |
|---------------|----------|----------|-----|------|
| Write command | Н | ↑ | L | L |
| Read status | ↑ | Н | L | L |
| Write data | Н | ↑ | L | Н |
| Read data | ↑ | Н | L | Н |

Note

- $^{(1)}$ \uparrow stands for rising edge of signal
- (2) H stands for HIGH in signal
- (3) L stands for LOW in signal

In order to match the operating frequency of display RAM with that of the microprocessor, some pipeline processing is internally performed which requires the insertion of a dummy read before the first actual display data read. This is shown in Figure 8-4.

Figure 8-4: Display data read back procedure - insertion of dummy read

8.1.3 MCU Serial Interface (4-wire SPI)

The 4-wire serial interface consists of serial clock: SCLK, serial data: SDIN, D/C#, CS#. In 4-wire SPI mode, D0 acts as SCLK, D1 acts as SDIN. For the unused data pins, D2 should be left open. The pins from D3 to D7, E and R/W# (WR#)# can be connected to an external ground.

Table 8-4: Control pins of 4-wire Serial interface

| Function | E(RD#) | R/W#(WR#) | CS# | D/C# | D0 |
|---------------|---------|-----------|-----|------|-----------|
| Write command | Tie LOW | Tie LOW | L | L | ↑ |
| Write data | Tie LOW | Tie LOW | L | Н | ↑ |

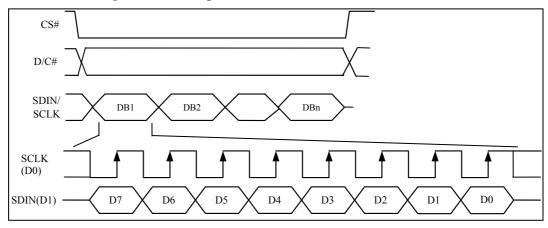

Note

- (1) H stands for HIGH in signal
- (2) L stands for LOW in signal

SDIN is shifted into an 8-bit shift register on every rising edge of SCLK in the order of D7, D6, ... D0. D/C# is sampled on every eighth clock and the data byte in the shift register is written to the Graphic Display Data RAM (GDDRAM) or command register in the same clock.

Under serial mode, only write operations are allowed.

Figure 8-5: Write procedure in 4-wire Serial interface mode

8.1.4 MCU Serial Interface (3-wire SPI)

The 3-wire serial interface consists of serial clock SCLK, serial data SDIN and CS#. In 3-wire SPI mode, D0 acts as SCLK, D1 acts as SDIN. For the unused data pins, D2 should be left open. The pins from D3 to D7, R/W# (WR#)#, E and D/C# can be connected to an external ground.

The operation is similar to 4-wire serial interface while D/C# pin is not used. There are altogether 9-bits will be shifted into the shift register on every ninth clock in sequence: D/C# bit, D7 to D0 bit. The D/C# bit (first bit of the sequential data) will determine the following data byte in the shift register is written to the Display Data RAM (D/C# bit = 1) or the command register (D/C# bit = 0). Under serial mode, only write operations are allowed.

Table 8-5: Control pins of 3-wire Serial interface

| Function | E(RD#) | R/W#(WR#) | CS# | D/C# | D0 |
|---------------|---------|-----------|-----|---------|----------|
| Write command | Tie LOW | Tie LOW | L | Tie LOW | ↑ |
| Write data | Tie LOW | Tie LOW | L | Tie LOW | ↑ |

Figure 8-6: Write procedure in 3-wire Serial interface mode

Solomon Systech Apr 2008 | P 18/59 | Rev 1.1 | SSD1306

8.1.5 MCU I²C Interface

The I^2C communication interface consists of slave address bit SA0, I^2C -bus data signal SDA (SDA_{OUT}/D₂ for output and SDA_{IN}/D₁ for input) and I^2C -bus clock signal SCL (D₀). Both the data and clock signals must be connected to pull-up resistors. RES# is used for the initialization of device.

a) Slave address bit (SA0)

SSD1306 has to recognize the slave address before transmitting or receiving any information by the I^2C -bus. The device will respond to the slave address following by the slave address bit ("SA0" bit) and the read/write select bit ("R/W#" bit) with the following byte format,

 $b_7 \ b_6 \ b_5 \ b_4 \ b_3 \ b_2 \ b_1 \ b_0$

0 1 1 1 1 0 SA0 R/W#

"SA0" bit provides an extension bit for the slave address. Either "0111100" or "0111101", can be selected as the slave address of SSD1306. D/C# pin acts as SA0 for slave address selection.

"R/W#" bit is used to determine the operation mode of the I^2C -bus interface. R/W#=1, it is in read mode. R/W#=0, it is in write mode.

b) I²C-bus data signal (SDA)

SDA acts as a communication channel between the transmitter and the receiver. The data and the acknowledgement are sent through the SDA.

It should be noticed that the ITO track resistance and the pulled-up resistance at "SDA" pin becomes a voltage potential divider. As a result, the acknowledgement would not be possible to attain a valid logic 0 level in "SDA".

"SDA_{IN}" and "SDA_{OUT}" are tied together and serve as SDA. The "SDA_{IN}" pin must be connected to act as SDA. The "SDA_{OUT}" pin may be disconnected. When "SDA_{OUT}" pin is disconnected, the acknowledgement signal will be ignored in the I^2 C-bus.

c) I²C-bus clock signal (SCL)

The transmission of information in the I²C-bus is following a clock signal, SCL. Each transmission of data bit is taken place during a single clock period of SCL.

8.1.5.1 I²C-bus Write data

The I²C-bus interface gives access to write data and command into the device. Please refer to Figure 8-7 for the write mode of I²C-bus in chronological order.

Note: Co - Continuation bit D/C# - Data / Command Selection bit ACK - Acknowledgement SA0 - Slave address bit R/W# - Read / Write Selection bit $S-Start\ Condition\ /\ P-Stop\ Condition$ Write mode Slave Address 1 byte $n \ge 0$ bytes m > 0 words MSBLSB $\mathsf{I} \mathsf{I} \mathsf{I}$ SSD1306 Slave Address Control byte

Figure 8-7: I²C-bus data format

8.1.5.2 Write mode for I^2C

- 1) The master device initiates the data communication by a start condition. The definition of the start condition is shown in Figure 8-8. The start condition is established by pulling the SDA from HIGH to LOW while the SCL stays HIGH.
- 2) The slave address is following the start condition for recognition use. For the SSD1306, the slave address is either "b0111100" or "b0111101" by changing the SA0 to LOW or HIGH (D/C pin acts as SA0)
- 3) The write mode is established by setting the R/W# bit to logic "0".
- 4) An acknowledgement signal will be generated after receiving one byte of data, including the slave address and the R/W# bit. Please refer to the Figure 8-9 for the graphical representation of the acknowledge signal. The acknowledge bit is defined as the SDA line is pulled down during the HIGH period of the acknowledgement related clock pulse.
- 5) After the transmission of the slave address, either the control byte or the data byte may be sent across the SDA. A control byte mainly consists of Co and D/C# bits following by six "0" 's.
 - a. If the Co bit is set as logic "0", the transmission of the following information will contain data bytes only.
 - b. The D/C# bit determines the next data byte is acted as a command or a data. If the D/C# bit is set to logic "0", it defines the following data byte as a command. If the D/C# bit is set to logic "1", it defines the following data byte as a data which will be stored at the GDDRAM. The GDDRAM column address pointer will be increased by one automatically after each data write.
- 6) Acknowledge bit will be generated after receiving each control byte or data byte.
- 7) The write mode will be finished when a stop condition is applied. The stop condition is also defined in Figure 8-8. The stop condition is established by pulling the "SDA in" from LOW to HIGH while the "SCL" stays HIGH.

Solomon Systech Apr 2008 | P 20/59 | Rev 1.1 | SSD1306

Figure 8-8: Definition of the Start and Stop Condition

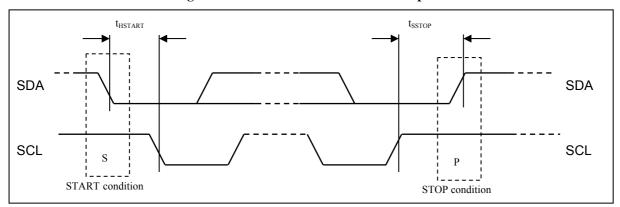

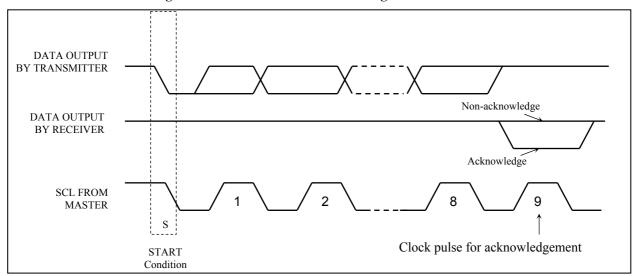

Figure 8-9: Definition of the acknowledgement condition

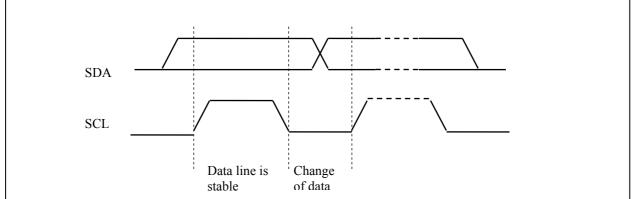

Please be noted that the transmission of the data bit has some limitations.

1. The data bit, which is transmitted during each SCL pulse, must keep at a stable state within the "HIGH" period of the clock pulse. Please refer to the Figure 8-10 for graphical representations. Except in start or stop conditions, the data line can be switched only when the SCL is LOW.

Figure 8-10: Definition of the data transfer condition

2. Both the data line (SDA) and the clock line (SCL) should be pulled up by external resistors.

P 21/59 SSD1306 Rev 1.1 Apr 2008 Solomon Systech

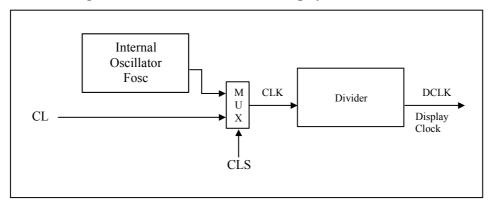

8.2 Command Decoder

This module determines whether the input data is interpreted as data or command. Data is interpreted based upon the input of the D/C# pin.

If D/C# pin is HIGH, D[7:0] is interpreted as display data written to Graphic Display Data RAM (GDDRAM). If it is LOW, the input at D[7:0] is interpreted as a command. Then data input will be decoded and written to the corresponding command register.

8.3 Oscillator Circuit and Display Time Generator

Figure 8-11: Oscillator Circuit and Display Time Generator

This module is an on-chip LOW power RC oscillator circuitry. The operation clock (CLK) can be generated either from internal oscillator or external source CL pin. This selection is done by CLS pin. If CLS pin is pulled HIGH, internal oscillator is chosen and CL should be left open. Pulling CLS pin LOW disables internal oscillator and external clock must be connected to CL pins for proper operation. When the internal oscillator is selected, its output frequency Fosc can be changed by command D5h A[7:4].

The display clock (DCLK) for the Display Timing Generator is derived from CLK. The division factor "D" can be programmed from 1 to 16 by command D5h

$$DCLK = F_{OSC} / D$$

The frame frequency of display is determined by the following formula.

$$F_{FRM} = \frac{F_{osc}}{D \times K \times No. \text{ of Mux}}$$

where

- D stands for clock divide ratio. It is set by command D5h A[3:0]. The divide ratio has the range from 1 to 16.
- K is the number of display clocks per row. The value is derived by

K = Phase 1 period + Phase 2 period + BANK0 pulse width

= 2 + 2 + 50 = 54 at power on reset

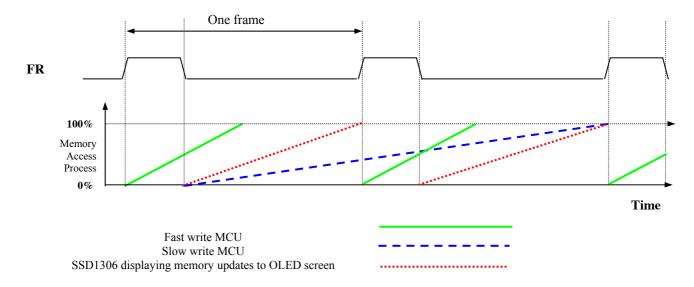

(Please refer to Section 8.6 "Segment Drivers / Common Drivers" for the details of the "Phase")

- Number of multiplex ratio is set by command A8h. The power on reset value is 63 (i.e. 64MUX).
- F_{OSC} is the oscillator frequency. It can be changed by command D5h A[7:4]. The higher the register setting results in higher frequency.

Solomon Systech Apr 2008 | P 22/59 | Rev 1.1 | SSD1306

8.4 FR synchronization

FR synchronization signal can be used to prevent tearing effect.

The starting time to write a new image to OLED driver is depended on the MCU writing speed. If MCU can finish writing a frame image within one frame period, it is classified as fast write MCU. For MCU needs longer writing time to complete (more than one frame but within two frames), it is a slow write one.

For fast write MCU: MCU should start to write new frame of ram data just after rising edge of FR pulse and should be finished well before the rising edge of the next FR pulse.

For slow write MCU: MCU should start to write new frame ram data after the falling edge of the 1st FR pulse and must be finished before the rising edge of the 3rd FR pulse.

8.5 Reset Circuit

When RES# input is LOW, the chip is initialized with the following status:

- 1. Display is OFF
- 2. 128 x 64 Display Mode
- 3. Normal segment and display data column address and row address mapping (SEG0 mapped to address 00h and COM0 mapped to address 00h)
- 4. Shift register data clear in serial interface
- 5. Display start line is set at display RAM address 0
- 6. Column address counter is set at 0
- 7. Normal scan direction of the COM outputs
- 8. Contrast control register is set at 7Fh
- 9. Normal display mode (Equivalent to A4h command)

8.6 Segment Drivers / Common Drivers

Segment drivers deliver 128 current sources to drive the OLED panel. The driving current can be adjusted from 0 to 100uA with 256 steps. Common drivers generate voltage-scanning pulses.

The segment driving waveform is divided into three phases:

- 1. In phase 1, the OLED pixel charges of previous image are discharged in order to prepare for next image content display.
- 2. In phase 2, the OLED pixel is driven to the targeted voltage. The pixel is driven to attain the corresponding voltage level from V_{SS} . The period of phase 2 can be programmed in length from 1 to 15 DCLKs. If the capacitance value of the pixel of OLED panel is larger, a longer period is required to charge up the capacitor to reach the desired voltage.
- 3. In phase 3, the OLED driver switches to use current source to drive the OLED pixels and this is the current drive stage.

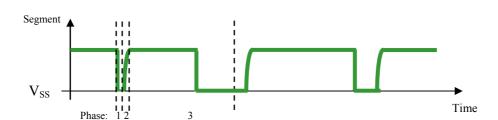

Figure 8-12 : Segment Output Waveform in three phases

After finishing phase 3, the driver IC will go back to phase 1 to display the next row image data. This three-step cycle is run continuously to refresh image display on OLED panel.

In phase 3, if the length of current drive pulse width is set to 50, after finishing 50 DCLKs in current drive phase, the driver IC will go back to phase 1 for next row display.

Solomon Systech Apr 2008 | P 24/59 | Rev 1.1 | SSD1306

8.7 Graphic Display Data RAM (GDDRAM)

The GDDRAM is a bit mapped static RAM holding the bit pattern to be displayed. The size of the RAM is 128 x 64 bits and the RAM is divided into eight pages, from PAGE0 to PAGE7, which are used for monochrome 128x64 dot matrix display, as shown in Figure 8-13.

Row re-mapping PAGE0 (COM0-COM7) PAGE0 (COM 63-COM56) Page 0 PAGE1 (COM8-COM15) PAGE1 (COM 55-COM48) Page 1 PAGE2 (COM47-COM40) PAGE2 (COM16-COM23) Page 2 PAGE3 (COM24-COM31) PAGE3 (COM39-COM32) Page 3 PAGE4 (COM32-COM39) PAGE4 (COM31-COM24) Page 4 PAGE5 (COM40-COM47) PAGE5 (COM23-COM16) Page 5 PAGE6 (COM48-COM55) PAGE6 (COM15-COM8) Page 6 PAGE7 (COM56-COM63) PAGE7 (COM 7-COM0) Page 7 SEG0 -----SEG127 Column re-mapping

Figure 8-13: GDDRAM pages structure of SSD1306

When one data byte is written into GDDRAM, all the rows image data of the same page of the current column are filled (i.e. the whole column (8 bits) pointed by the column address pointer is filled.). Data bit D0 is written into the top row, while data bit D7 is written into bottom row as shown in Figure 8-14.

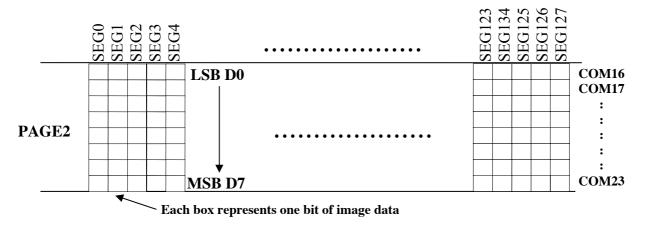

Figure 8-14: Enlargement of GDDRAM (No row re-mapping and column-remapping)

For mechanical flexibility, re-mapping on both Segment and Common outputs can be selected by software as shown in Figure 8-13.

For vertical shifting of the display, an internal register storing the display start line can be set to control the portion of the RAM data to be mapped to the display (command D3h).

8.8 SEG/COM Driving block

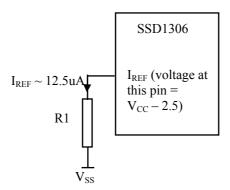

This block is used to derive the incoming power sources into the different levels of internal use voltage and current.

- V_{CC} is the most positive voltage supply.
- V_{COMH} is the Common deselected level. It is internally regulated.
- V_{LSS} is the ground path of the analog and panel current.
- I_{REF} is a reference current source for segment current drivers I_{SEG}. The relationship between reference current and segment current of a color is:

```
I_{SEG} = Contrast \, / \, 256 \, x \, I_{REF} \, x \, scale \, factor in which the \, contrast \, (0{\sim}255) \, is \, set \, by \, Set \, Contrast \, command \, 81h; \, and \\ the \, scale \, factor \, is \, 8 \, by \, default.
```

The magnitude of I_{REF} is controlled by the value of resistor, which is connected between I_{REF} pin and V_{SS} as shown in Figure 8-15. It is recommended to set I_{REF} to 12.5 \pm 2uA so as to achieve I_{SEG} = 100uA at maximum contrast 255.

Figure 8-15: I_{REF} Current Setting by Resistor Value

Since the voltage at I_{REF} pin is $V_{CC} - 2.5V$, the value of resistor R1 can be found as below:

R1 = (Voltage at $I_{REF} - V_{SS}$) / I_{REF} = (12 - 2.5) / 12.5uA = 760KΩ

For $I_{REF} = 12.5uA$, $V_{CC} = 12V$:

Solomon Systech Apr 2008 | P 26/59 | Rev 1.1 | SSD1306

8.9 Power ON and OFF sequence

The following figures illustrate the recommended power ON and power OFF sequence of SSD1306

Power ON sequence:

- 1. Power ON V_{DD}
- 2. After V_{DD} become stable, set RES# pin LOW (logic low) for at least 3us (t₁) ⁽⁴⁾ and then HIGH (logic high).
- 3. After set RES# pin LOW (logic low), wait for at least 3us (t_2). Then Power ON V_{CC} ⁽¹⁾
- 4. After V_{CC} become stable, send command AFh for display ON. SEG/COM will be ON after 100ms (t_{AF}).

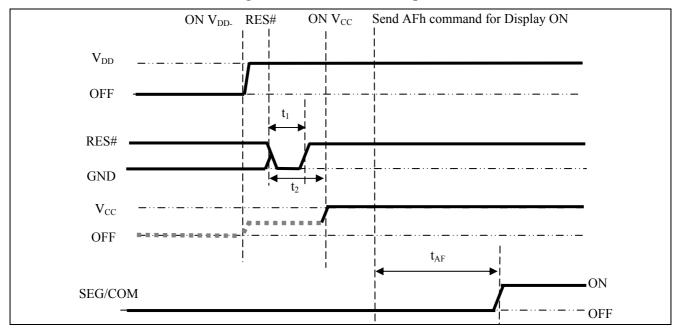

Figure 8-16: The Power ON sequence

Power OFF sequence:

- 1. Send command AEh for display OFF.
- 2. Power OFF $V_{CC}^{(1),(2),(3)}$
- 3. Power OFF V_{DD} after t_{OFF}. (Typical t_{OFF}=100ms)

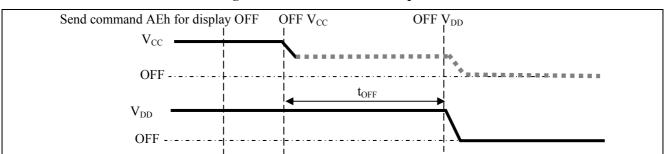

Figure 8-17: The Power OFF sequence

Note:

- ⁽¹⁾ Since an ESD protection circuit is connected between V_{DD} and V_{CC} , V_{CC} becomes lower than V_{DD} whenever V_{DD} is ON and V_{CC} is OFF as shown in the dotted line of V_{CC} in Figure 8-16 and Figure 8-17.
- $^{(2)}V_{CC}$ should be kept float (i.e. disable) when it is OFF.
- $^{(3)}$ Power Pins (V_{DD} , V_{CC}) can never be pulled to ground under any circumstance.
- $^{(4)}$ The register values are reset after t_1 .
- $^{(5)}$ V_{DD} should not be Power OFF before V_{CC} Power OFF.

| | | D[3]: | Reserved |
| | | D[2]: | Reserved |
| | | D[1] : | Reserved |
| | | D[0]: | Reserved |

Note

9.1 Data Read / Write

To read data from the GDDRAM, select HIGH for both the R/W# (WR#) pin and the D/C# pin for 6800-series parallel mode and select LOW for the E (RD#) pin and HIGH for the D/C# pin for 8080-series parallel mode. No data read is provided in serial mode operation.

In normal data read mode the GDDRAM column address pointer will be increased automatically by one after each data read.

Also, a dummy read is required before the first data read.

To write data to the GDDRAM, select LOW for the R/W# (WR#) pin and HIGH for the D/C# pin for both 6800-series parallel mode and 8080-series parallel mode. The serial interface mode is always in write mode. The GDDRAM column address pointer will be increased automatically by one after each data write.

Table 9-3: Address increment table (Automatic)

| D/C# | R/W# (WR#) | Comment | Address Increment |
|------|------------|---------------|-------------------|
| 0 | 0 | Write Command | No |
| 0 | 1 | Read Status | No |
| 1 | 0 | Write Data | Yes |
| 1 | 1 | Read Data | Yes |

⁽¹⁾ Patterns other than those given in the Command Table are prohibited to enter the chip as a command; as unexpected results can occur.

10 COMMAND DESCRIPTIONS

10.1 Fundamental Command

10.1.1 Set Lower Column Start Address for Page Addressing Mode (00h~0Fh)

This command specifies the lower nibble of the 8-bit column start address for the display data RAM under Page Addressing Mode. The column address will be incremented by each data access. Please refer to Section Table 9-1 and Section 10.1.3 for details.

10.1.2 Set Higher Column Start Address for Page Addressing Mode (10h~1Fh)

This command specifies the higher nibble of the 8-bit column start address for the display data RAM under Page Addressing Mode. The column address will be incremented by each data access. Please refer to Section Table 9-1 and Section 10.1.3 for details.

10.1.3 Set Memory Addressing Mode (20h)

There are 3 different memory addressing mode in SSD1306: page addressing mode, horizontal addressing mode and vertical addressing mode. This command sets the way of memory addressing into one of the above three modes. In there, "COL" means the graphic display data RAM column.

Page addressing mode (A[1:0]=10xb)

In page addressing mode, after the display RAM is read/written, the column address pointer is increased automatically by 1. If the column address pointer reaches column end address, the column address pointer is reset to column start address and page address pointer is not changed. Users have to set the new page and column addresses in order to access the next page RAM content. The sequence of movement of the PAGE and column address point for page addressing mode is shown in Figure 10-1.

 COL 1

 COL 126
 COL 127

 PAGE0
 →
 →
 →

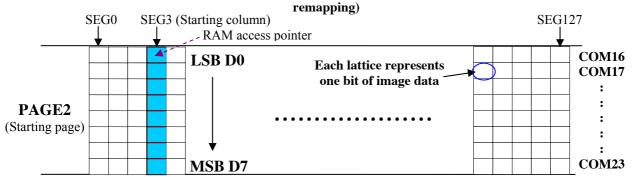

Figure 10-1: Address Pointer Movement of Page addressing mode

In normal display data RAM read or write and page addressing mode, the following steps are required to define the starting RAM access pointer location:

- Set the page start address of the target display location by command B0h to B7h.
- Set the lower start column address of pointer by command 00h~0Fh.
- Set the upper start column address of pointer by command 10h~1Fh.

For example, if the page address is set to B2h, lower column address is 03h and upper column address is 10h, then that means the starting column is SEG3 of PAGE2. The RAM access pointer is located as shown in Figure 10-2. The input data byte will be written into RAM position of column 3.

Figure 10-2 : Example of GDDRAM access pointer setting in Page Addressing Mode (No row and column-

 Solomon Systech
 Apr 2008
 P 34/59
 Rev 1.1
 SSD1306

Horizontal addressing mode (A[1:0]=00b)

In horizontal addressing mode, after the display RAM is read/written, the column address pointer is increased automatically by 1. If the column address pointer reaches column end address, the column address pointer is reset to column start address and page address pointer is increased by 1. The sequence of movement of the page and column address point for horizontal addressing mode is shown in Figure 10-3. When both column and page address pointers reach the end address, the pointers are reset to column start address and page start address (Dotted line in Figure 10-3.)

PAGE0
PAGE1

PAGE6
PAGE7

COL 1 COL 126 COL 127

Figure 10-3: Address Pointer Movement of Horizontal addressing mode

Vertical addressing mode: (A[1:0]=01b)

In vertical addressing mode, after the display RAM is read/written, the page address pointer is increased automatically by 1. If the page address pointer reaches the page end address, the page address pointer is reset to page start address and column address pointer is increased by 1. The sequence of movement of the page and column address point for vertical addressing mode is shown in Figure 10-4. When both column and page address pointers reach the end address, the pointers are reset to column start address and page start address (Dotted line in Figure 10-4.)

Figure 10-4: Address Pointer Movement of Vertical addressing mode

In normal display data RAM read or write and horizontal / vertical addressing mode, the following steps are required to define the RAM access pointer location:

- Set the column start and end address of the target display location by command 21h.
- Set the page start and end address of the target display location by command 22h.

Example is shown in Figure 10-5.

10.1.4 Set Column Address (21h)

This triple byte command specifies column start address and end address of the display data RAM. This command also sets the column address pointer to column start address. This pointer is used to define the current read/write column address in graphic display data RAM. If horizontal address increment mode is enabled by command 20h, after finishing read/write one column data, it is incremented automatically to the next column address. Whenever the column address pointer finishes accessing the end column address, it is reset back to start column address and the row address is incremented to the next row.

10.1.5 Set Page Address (22h)

This triple byte command specifies page start address and end address of the display data RAM. This command also sets the page address pointer to page start address. This pointer is used to define the current read/write page address in graphic display data RAM. If vertical address increment mode is enabled by command 20h, after finishing read/write one page data, it is incremented automatically to the next page address. Whenever the page address pointer finishes accessing the end page address, it is reset back to start page address.

The figure below shows the way of column and page address pointer movement through the example: column start address is set to 2 and column end address is set to 125, page start address is set to 1 and page end address is set to 6; Horizontal address increment mode is enabled by command 20h. In this case, the graphic display data RAM column accessible range is from column 2 to column 125 and from page 1 to page 6 only. In addition, the column address pointer is set to 2 and page address pointer is set to 1. After finishing read/write one pixel of data, the column address is increased automatically by 1 to access the next RAM location for next read/write operation (*solid line in Figure 10-5*). Whenever the column address pointer finishes accessing the end column 125, it is reset back to column 2 and page address is automatically increased by 1 (*solid line in Figure 10-5*). While the end page 6 and end column 125 RAM location is accessed, the page address is reset back to 1 and the column address is reset back to 2 (*dotted line in Figure 10-5*).

PAGE0
PAGE1
:
PAGE6
PAGE7

Figure 10-5: Example of Column and Row Address Pointer Movement

10.1.6 Set Display Start Line (40h~7Fh)

This command sets the Display Start Line register to determine starting address of display RAM, by selecting a value from 0 to 63. With value equal to 0, RAM row 0 is mapped to COM0. With value equal to 1, RAM row 1 is mapped to COM0 and so on.

Refer to Table 10-1 for more illustrations.

10.1.7 Set Contrast Control for BANK0 (81h)

This command sets the Contrast Setting of the display. The chip has 256 contrast steps from 00h to FFh. The segment output current increases as the contrast step value increases.

10.1.8 Set Segment Re-map (A0h/A1h)

This command changes the mapping between the display data column address and the segment driver. It allows flexibility in OLED module design. Please refer to Table 9-1.

This command only affects subsequent data input. Data already stored in GDDRAM will have no changes.

Solomon Systech Apr 2008 | P 36/59 | Rev 1.1 | SSD1306

10.1.9 Entire Display ON (A4h/A5h)

A4h command enable display outputs according to the GDDRAM contents.

If A5h command is issued, then by using A4h command, the display will resume to the GDDRAM contents. In other words, A4h command resumes the display from entire display "ON" stage.

A5h command forces the entire display to be "ON", regardless of the contents of the display data RAM.

10.1.10 Set Normal/Inverse Display (A6h/A7h)

This command sets the display to be either normal or inverse. In normal display a RAM data of 1 indicates an "ON" pixel while in inverse display a RAM data of 0 indicates an "ON" pixel.

10.1.11 Set Multiplex Ratio (A8h)

This command switches the default 63 multiplex mode to any multiplex ratio, ranging from 16 to 63. The output pads COM0~COM63 will be switched to the corresponding COM signal.

10.1.12 Set Display ON/OFF (AEh/AFh)

These single byte commands are used to turn the OLED panel display ON or OFF.

When the display is ON, the selected circuits by Set Master Configuration command will be turned ON. When the display is OFF, those circuits will be turned OFF and the segment and common output are in V_{SS} state and high impedance state, respectively. These commands set the display to one of the two states:

AEh : Display OFFAFh : Display ON

Figure 10-6: Transition between different modes

10.1.13 Set Page Start Address for Page Addressing Mode (B0h~B7h)

This command positions the page start address from 0 to 7 in GDDRAM under Page Addressing Mode. Please refer to Table 9-1 and Section 10.1.3 for details.

10.1.14 Set COM Output Scan Direction (C0h/C8h)

This command sets the scan direction of the COM output, allowing layout flexibility in the OLED module design. Additionally, the display will show once this command is issued. For example, if this command is sent during normal display then the graphic display will be vertically flipped immediately. Please refer to Table 10-3 for details.

10.1.15 Set Display Offset (D3h)

This is a double byte command. The second command specifies the mapping of the display start line to one of COM0~COM63 (assuming that COM0 is the display start line then the display start line register is equal to 0).

For example, to move the COM16 towards the COM0 direction by 16 lines the 6-bit data in the second byte should be given as 010000b. To move in the opposite direction by 16 lines the 6-bit data should be given by 64 - 16, so the second byte would be 100000b. The following two tables (Table 10-1, Table 10-2) show the example of setting the command C0h/C8h and D3h.

Table 10-1: Example of Set Display Offset and Display Start Line with no Remap

| | | | | | | Out | | | | | | | |

SSD1306 Rev 1.1 P 39/59 Apr 2008 **Solomon Systech**

10.1.16 Set Display Clock Divide Ratio/ Oscillator Frequency (D5h)

This command consists of two functions:

- Display Clock Divide Ratio (D)(A[3:0])
 Set the divide ratio to generate DCLK (Display Clock) from CLK. The divide ratio is from 1 to 16, with reset value = 1. Please refer to section 8.3 for the details relationship of DCLK and CLK.
- Oscillator Frequency (A[7:4])
 Program the oscillator frequency Fosc that is the source of CLK if CLS pin is pulled high. The 4-bit value results in 16 different frequency settings available as shown below. The default setting is 1000b.

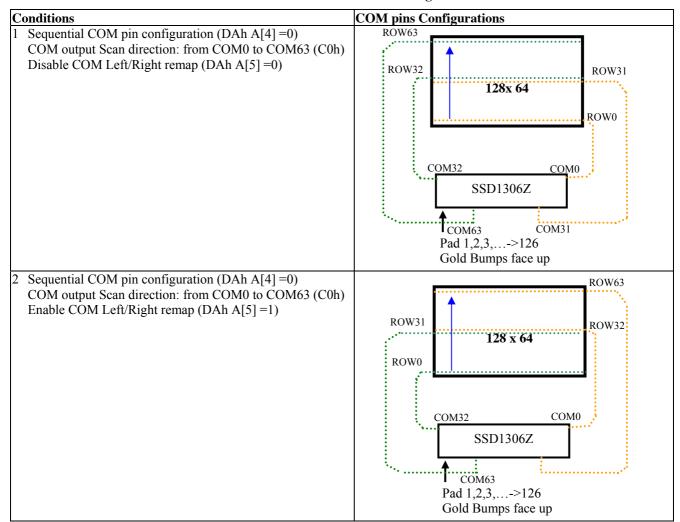

10.1.17 Set Pre-charge Period (D9h)

This command is used to set the duration of the pre-charge period. The interval is counted in number of DCLK, where RESET equals 2 DCLKs.

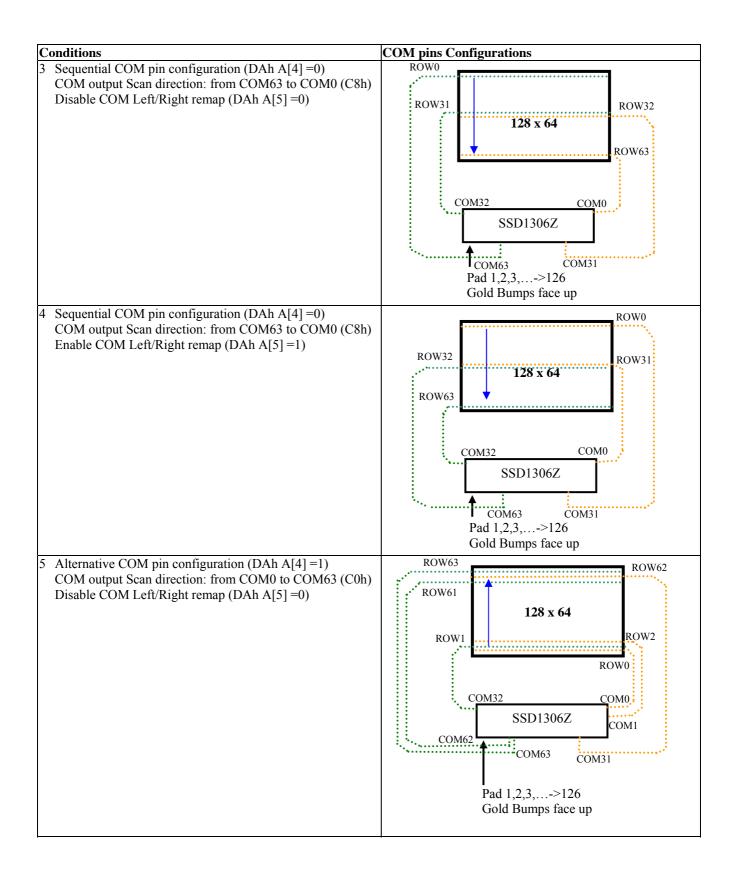

10.1.18 Set COM Pins Hardware Configuration (DAh)

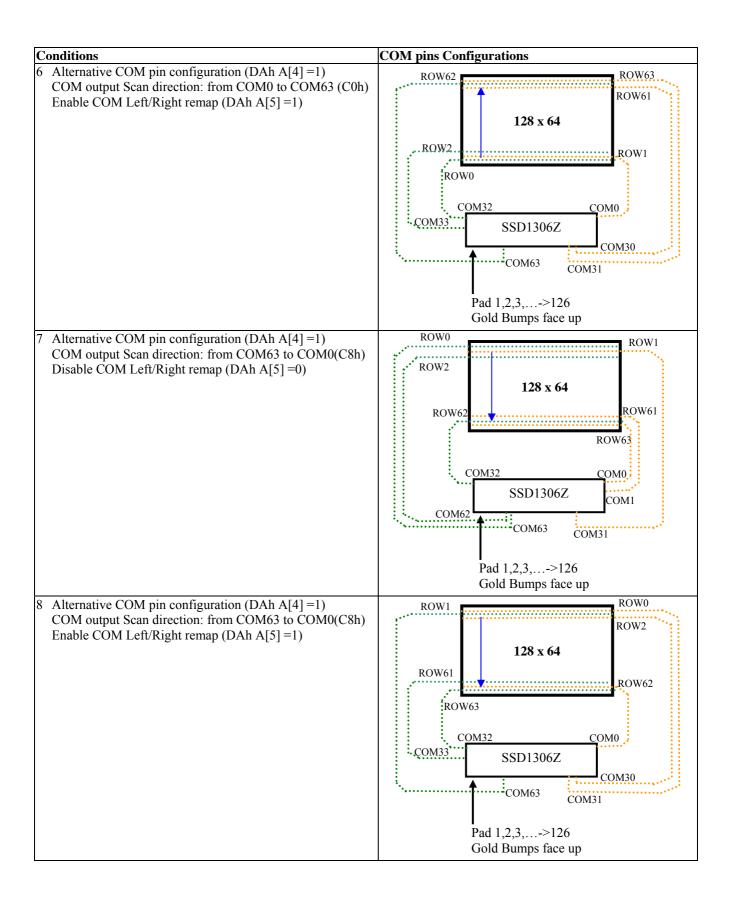

This command sets the COM signals pin configuration to match the OLED panel hardware layout. The table below shows the COM pin configuration under different conditions (for MUX ratio =64):

Table 10-3: COM Pins Hardware Configuration

10.1.19 Set V_{COMH} Deselect Level (DBh)

This command adjusts the V_{COMH} regulator output.

10.1.20 NOP (E3h)

No Operation Command

10.1.21 Status register Read

This command is issued by setting D/C# ON LOW during a data read (See Figure 13-1 to Figure 13-2 for parallel interface waveform). It allows the MCU to monitor the internal status of the chip. No status read is provided for serial mode.

SSD1306 Rev 1.1 P 43/59 Apr 2008 **Solomon Systech**

10.2 Graphic Acceleration Command

10.2.1 Horizontal Scroll Setup (26h/27h)

This command consists of consecutive bytes to set up the horizontal scroll parameters and determines the scrolling start page, end page and scrolling speed.

Before issuing this command the horizontal scroll must be deactivated (2Eh). Otherwise, RAM content may be corrupted.

The SSD1306 horizontal scroll is designed for 128 columns scrolling. The following two figures (Figure 10-7, Figure 10-8, Figure 10-9) show the examples of using the horizontal scroll:

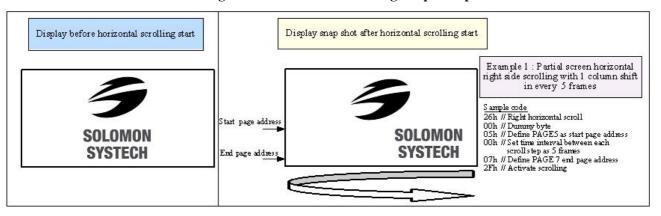

Figure 10-7: Horizontal scroll example: Scroll RIGHT by 1 column

| Original Setting | SEG0 | SEG1 | SEG2 | SEG3 | SEG4 | SEG5 | : | ÷ | : | SEG122 | SEG123 | SEG124 | SEG125 | SEG126 | SEG127 |
|-----------------------|--------|------|------|------|------|------|---|---|---|--------|--------|--------|--------|--------|--------|
| After one scroll step | SEG127 | SEG0 | SEG1 | SEG2 | SEG3 | SEG4 | : | : | : | SEG121 | SEG122 | SEG123 | SEG124 | SEG125 | SEG126 |

Figure 10-8: Horizontal scroll example: Scroll LEFT by 1 column

| Original Setting | SEG0 | SEG1 | SEG2 | SEG3 | SEG4 | SEG5 | : | : | SEG122 | SEG123 | SEG124 | SEG125 | SEG126 | SEG127 |
|-----------------------|------|------|------|------|------|------|----|-------|--------|--------|--------|--------|--------|--------|
| After one scroll step | SEG1 | SEG2 | SEG3 | SEG4 | SEGS | SEG6 | :: | | SEG123 | SEG124 | SEG125 | SEG126 | SEG127 | SEG0 |

Figure 10-9: Horizontal scrolling setup example

Solomon Systech Apr 2008 | P 44/59 | Rev 1.1 | SSD1306

10.2.2 Continuous Vertical and Horizontal Scroll Setup (29h/2Ah)

This command consists of 6 consecutive bytes to set up the continuous vertical scroll parameters and determines the scrolling start page, end page, scrolling speed and vertical scrolling offset.

The bytes B[2:0], C[2:0] and D[2:0] of command 29h/2Ah are for the setting of the continuous horizontal scrolling. The byte E[5:0] is for the setting of the continuous vertical scrolling offset. All these bytes together are for the setting of continuous diagonal (horizontal + vertical) scrolling. If the vertical scrolling offset byte E[5:0] is set to zero, then only horizontal scrolling is performed (like command 26/27h).

Before issuing this command the scroll must be deactivated (2Eh). Otherwise, RAM content may be corrupted. The following figure (Figure 10-10) show the example of using the continuous vertical and horizontal scroll:

Example 1 : Full screen diagonal Display before scrolling start Display snap shot after scrolling start scrolling (horizontal right side scrolling with 1 column shift plus Start page address/ vertical scrolling with 1 row up) in every 6 frames. No. of rows in top fixed area =0 (POR) Sample code 29h // Vertical and right horizontal scroll No. of rows in scroll 00h // Dummybyte 00h // Define PAGEO as start page address 00h // Set time interval between each area =64 (POR) scroll step as 6 frames 07h // Define PAGE7 as end page address End page address Olh #Set vertical scrolling offset as 1 row 2Fh // Activate scrolling

Figure 10-10: Continuous Vertical and Horizontal scrolling setup example

10.2.3 Deactivate Scroll (2Eh)

This command stops the motion of scrolling. After sending 2Eh command to deactivate the scrolling action, the ram data needs to be rewritten.

10.2.4 Activate Scroll (2Fh)

This command starts the motion of scrolling and should only be issued after the scroll setup parameters have been defined by the scrolling setup commands: 26h/27h/29h/2Ah. The setting in the last scrolling setup command overwrites the setting in the previous scrolling setup commands.

The following actions are prohibited after the scrolling is activated

- 1. RAM access (Data write or read)
- 2. Changing the horizontal scroll setup parameters

10.2.5 Set Vertical Scroll Area(A3h)

This command consists of 3 consecutive bytes to set up the vertical scroll area. For the continuous vertical scroll function (command 29/2Ah), the number of rows that in vertical scrolling can be set smaller or equal to the MUX ratio.

Solomon Systech Apr 2008 | P 46/59 | Rev 1.1 | SSD1306

11 MAXIMUM RATINGS

Table 11-1: Maximum Ratings (Voltage Referenced to VSS)

| Symbol | Parameter | Value | Unit |
|-----------------|---------------------------|--------------------------------|------|
| $V_{ m DD}$ | Supply Voltage | -0.3 to +4 | V |
| V_{CC} | Supply voltage | 0 to 16 | V |
| V_{SEG} | SEG output voltage | 0 to V _{CC} | V |
| V_{COM} | COM output voltage | 0 to 0.9*V _{CC} | V |
| V _{in} | Input voltage | V_{SS} -0.3 to V_{DD} +0.3 | V |
| T_A | Operating Temperature | -40 to +85 | °C |
| T_{stg} | Storage Temperature Range | -65 to +150 | °C |

Maximum ratings are those values beyond which damages to the device may occur. Functional operation should be restricted to the limits in the Electrical Characteristics tables or Pin Description section

This device may be light sensitive. Caution should be taken to avoid exposure of this device to any light source during normal operation. This device is not radiation protected.

SSD1306 Rev 1.1 P 47/59 Apr 2008 **Solomon Systech**

Solomon Systech Jan 2009 P 2/6 Rev 0.4 SSD1306 App note

1 Introduction

This application note of SSD1306 is written to explain the charge pump regulator function of SSD1306. SSD1306 is a single-chip CMOS OLED/PLED driver with controller for organic / polymer light emitting diode dot-matrix graphic display system. It consists of 128 segments and 64 commons. This IC is designed for Common Cathode type OLED panel.

For the detailed characteristics of the driver IC, please refer to SSD1306 datasheet.

2 Charge Pump Regulator

The internal regulator circuit in SSD1306 accompanying only 2 external capacitors can generate a 7.5V voltage supply, V_{CC} , from a low voltage supply input, V_{BAT} . The V_{CC} is the voltage supply to the OLED driver block. This is a switching capacitor regulator circuit, designed for handheld applications. This regulator can be turned on/off by software command setting.

Power supply

o $V_{DD} = 1.65V$ to 3.3V, $< V_{BAT}$ for IC logic

 \circ V_{BAT} = 3.3V to 4.2V for charge pump regulator circuit

Pins description for related pins of the charge pump regulator

V_{BAT} – Power supply for charge pump regulator circuit.

| DAI | | 1 | | |
|-------------|------------------------------|------------------------|--|--|
| Status | V_{BAT} | V_{DD} | Vcc | |

3 Software Configuration

SSD1306 has internal command registers that are used to configure the operations of the driver IC. After reset, the registers should be set with appropriate values in order to function well. The registers can be accessed by MPU interface in either 6800, 8080, SPI type with D/C# pin pull low or using I²C interface. Below is an example of initialization flow of SSD1306. The values of registers depend on different condition and application.

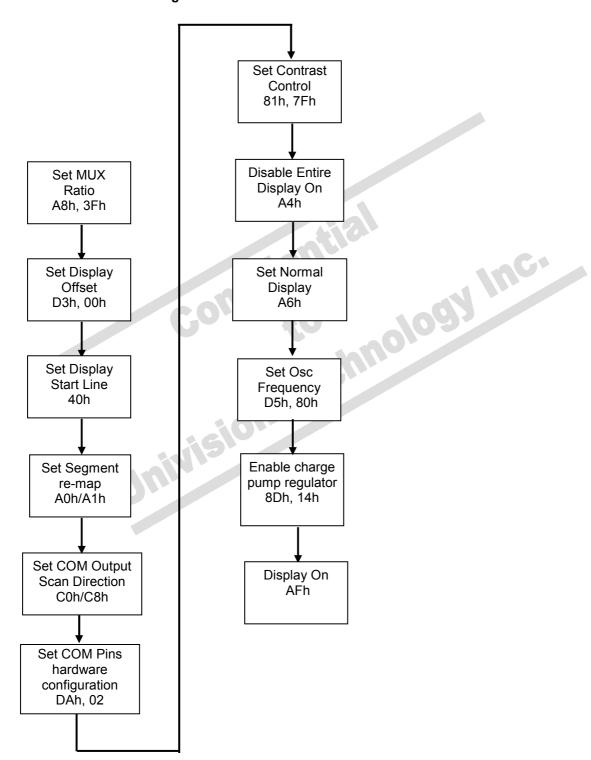

Figure 2 : Software Initialization Flow Chart
